

television 600 on time indicated by the PTS information.

That is, the point of time when to convert the audio and video data stream reproduced from a read-only DVD is determined based on the DTS and PTS written in the PES header of each PES, so that the converted analog real audio and video signals can be presented to a viewer through a speaker and a screen of a general television without any discontinuity.

FIG. 3 shows an example of several electric home appliances connected each other through a digital interface such as the IEEE 1394 standard. The electric home appliances connected each other are a digital television (TV) 500; a set top box (STB) 200 for receiving RF broadcast signals, extracting a data stream belonging to a selected program from the broadcast signals, and transmitting the extracted stream to the digital TV 500; and a streamer 300 recording or reproducing a digital data stream to/from a rewritable digital versatile disk (DVD-RAM).

The streamer 300 comprises a stream recording unit 32 for recording transport packets, which constitutes a transport stream (TS) for a digital broadcast program, transmitted from the STB 200 connected through the IEEE 1394 standard in a rewritable DVD 31; a stream reproducing unit 33 for reproducing the TS recorded in the rewritable DVD 31; an interface unit 34 for transmitting the reproduced TS to the STB 200 and receiving a data stream from the STB 200 through the IEEE 1394 standard; a controller 35 for controlling the operations of the above elements; and a memory 35 storing data necessary for the control operation of the controller 35.

The streamer 300 configured as above records a digital data stream of broadcast programs received from the

STB 200 in a rewritable DVD in a pre-specified format, or divides a data stream reproduced from the rewritable DVD into transport packets and then transmits them to the STB 200 through the IEEE 1394 standard.

5 The STB 200 transmits the received transport packets to the digital TV 500, then the digital TV 500 decodes the transport packets to present high-quality video and audio. Such operations make it possible to record digital broadcast programs and reproduce them.

10 FIG. 4 is a pictorial representation showing a hierarchical structure of a data stream recorded in the rewritable DVD and packet arrival time (PAT) information recorded in each transport packet (TP).

As shown in FIG. 4, one or more stream objects (SOBs) 15 are recorded in a rewritable DVD. A single SOB is composed of many stream object units (SOBUs). Partial stream belonging to a single SOBU is written across several fixed-size sectors. Header information and several TPs are written in each sector.

20 The streamer 300 adds 4-byte PAT to each TP as shown in FIG. 4 when recording the received data stream. The 4-byte PAT consists of a 9-bit arrival timestamp (ATS) extension marked as 'ATS\_ext' and a 39-bit arrival timestamp base marked as 'ATS\_base' according to the MPEG 25 standard. The arrival time extension is a modulo-300 counter that is incremented at a rate of 27 MHz, whereas the arrival time base is incremented at a rate of 90 KHz.

The reason of recording the PAT in each packet as explained above is to transmit recorded packets at same 30 interval which transport packets are received at, and to use the recorded PAT as a position index when searching for the video data, especially the infra-coded picture data recorded in the rewritable DVD. The reason why the position

index is necessary is to point the starting point of each  
infra-coded video frame since the starting point may be  
located anywhere in a SOBU when the broadcast program is  
recorded as it is received. The position index is used to  
5 jump quickly between infra-coded video frames while a trick  
play is conducted.

For a recording format for a under-developing read-  
only HDVD, it may be considered to adopt the TS as the  
recording-format in consideration that a data stream  
10 reproduced from a HDVD-ROM is delivered directly to a  
digital TV which accepts TS-formatted data.

The HDVD-ROM is not for recording arbitrary broadcast  
programs but for providing a permanently-recorded program,  
so that a recorded stream can be divided into many high-  
15 density object units (HOBUs) when a HDVD-ROM is  
manufactured in order that each HOBUs may be corresponding  
to a GOP unit of the MPEG standard.

Each GOP unit always has a infra-coded picture at its  
leading part, therefore, it is possible to make a trick-  
20 play by reproducing infra-coded pictures only by jumping to  
each HOBUs whose position can be known from navigation  
information read at initial loading of a disk. That is, it  
is not required to access into transport packet layer,  
which means that it is not necessary to record PATs like as  
25 a REWRITABLE DVD to search for every infra-coded pictures  
for a trick play.

However, each transport packet should be transmitted  
at time interval specified when a program is recorded into  
a read-only disk to be presented without discontinuity or  
30 delay, therefore, time reference information to use as  
point of time when to transmit each packet is still  
required for a read-only disk.

However, if such time reference information is

written in every transport packet for a HDVD-ROM, the space for program data may be remarkably decreased.

Accordingly, a method for recording time information to use as a packet sending time reference without  
5 decreasing program recording area should be developed urgently.

#### SUMMARY OF THE INVENTION

It is an object of the present invention to provide a method for creating and recording transport time  
10 information of data recorded in high-density disk recording medium, which uses a program clock reference (PCR) inserted intermittently in transport packets as a transport time reference of a packet, or creates transport time reference information for a transport packet every data recording  
15 unit accommodating several transport packets, writes the created transport time reference information in the corresponding data recording unit, and uses the written information as a time reference for transmitting the transport packet belonging to a corresponding data  
20 recording unit.

The method for creating and recording transport time reference information for a disk recording medium according to the present invention records transport time reference information for an arbitrary transport packet in a  
25 recording unit such as a pack in the header of the pack or in the header of the arbitrary packet while grouping several transport packets into a pack when recording a program in the form of a transport packet, and, when reproducing a recorded program, detects a transport time  
30 reference based on the information recorded in the header of a pack or an arbitrary transport packet, and then

transmits the arbitrary transport packet at the detected time reference.

Also, the method for creating and recording transport time reference information for a high-density disk recording medium according to the present invention specifies a fixed-positioned, for example the first transport packet to include time information for a transport time reference, and records the transport time reference information in the header of the fixed-positioned transport packet or a pack, and, when reproducing recorded transport packets, transmits the fixed-positioned transport packet at time interval according the time information for that packet.

#### BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are included to provide a further understanding of the invention, illustrate the preferred embodiments of the invention, and together with the description, serve to explain the principles of the present invention.

In the drawings:

FIG. 1 is a block diagram of a digital versatile disk player and a general television which are connected each other;

FIG. 2 shows a hierarchical structure of a recorded data stream and time information, especially the presentation timestamp and decoding timestamp, recorded in a read-only disk such as a DVD-ROM.

FIG. 3 shows an example of several electric home appliances connected each other through a digital interface such as the IEEE 1394 standard;

FIG. 4 is a pictorial representation showing a

hierarchical structure of a data stream recorded in the rewritable DVD and packet arrival time information recorded in each transport packet;

FIG. 5 is a block diagram of a high-density DVD player and a digital television to which a method for creating and recording transport time reference information according to the present invention is applied;

FIG. 6 shows a hierarchical data structure and a recording example of transport time reference information for a data stream recorded in a HDVD-ROM according to the present invention;

FIG. 7 shows the recording position of a program clock reference (PCR) which is intermittently recorded in transport packets;

FIG. 8 is an example of transport time reference information recorded according to the present invention;

FIGS. 9 and 10 show another embodiment for creating and recording transport time reference information according to the present invention;

FIG. 11 is another embodiment for creating and recording transport time reference information according to the present invention; and

FIG. 12 is another embodiment for creating and recording transport time reference information according to the present invention.

PCR) which is intermittently recorded in transport packets;

#### **DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT**

In order that the invention may be fully understood, information recorded according to the present invention preferred embodiments thereof will now be described with reference to the accompanying drawings.

FIG. 5 is a block diagram of a HDVD player 400 and a digital television 500 which are connected each other. The

HDVD player 400, which reproduces video and audio data recorded in a HDVD-ROM 41, comprises an optical pickup 42 for detecting signals recorded in the ROM disk 41; an analog signal processor 43 for converting the detected  
5 high-frequency signals into binary signals; a digital signal processor 44 for processing the binary signals to restore them into a digital data stream; a TS MUX 45 for extracting transport packets from the restored data stream; and a controller 46 for controlling the data reproduction  
10 and data processing timing of each element.

The HDVD player 400 configured as FIG. 5 reproduces recorded data from the HDVD-ROM 41, extracts transport packets from reproduced data, and transmits the extracted transport packets to the digital TV 500 on time specified  
15 for each packet. The digital TV 500 decodes the received packets to present them to a viewer immediately after receiving them.

The data stream recorded in the HDVD-ROM 41 has a hierarchical data structure as shown in FIG. 6, and it has  
20 transport time reference information, of which format is also shown in FIG. 6, for transmitting transport packets to the digital television 500 at time reference difference interval which should be satisfied for continuous data presentation.

25 The hierarchical structure and the data syntax of FIG. 6 is explained in detail.

As shown in FIG. 6, one or more high-density video objects (HOBs) are recorded in a HDVD-ROM in a format of transport stream during manufacturing the ROM disk. A  
30 single HOB is corresponding to a single title or program and is composed of many high-density object units (HOBUs). A single HOB is composed of several packs marked as 'HD\_PCK' and always contains at least a GOP unit, which

always has infra-coded picture at its head part, of the MPEG standard. Each pack consists of a pack header, which contains management information for transport packets written in that pack, and several transport packets.

5       The management information recorded in the pack header includes the transport time reference information for recorded packets, and the transport time reference information is same with the PCR in both of format and function. The PCR is specified in the digital broadcast  
10 standard to be inserted in transport packets more than once during a few milliseconds in order that a data presenting machine such as a digital TV may adjust a local clock, which is used as a time reference on when to present received packets, synchronously with a program source clock  
15 of a broadcast station broadcasting TP-formatted programs. Accordingly, same as the PCR, the transport time reference information is written in transport packets every a few milliseconds which is specified in a digital broadcast standard when a program(or a title)-containing HDVD-ROM is  
20 manufactured.

      The format of the transport time reference information to be recorded in the pack header consists of a 9-bit extension time 'SYS\_PCR\_ext' and a 39-bit base time 'SYS\_PCR\_base' according to the MPEG standard. The  
25 extension time 'SYS\_PCR\_ext' is a modulo-300 counter that is incremented at a rate of 27 MHz, whereas the base time 'SYS\_PCR\_base' is incremented at a rate of 90 KHz.

      Whereas, the recording position to write PCR which can be used as a transport time reference is the optional  
30 field shown in FIG. 7. The optional field is optionally contained in the header of a transport packet.

      FIG. 8 is an example of transport time reference information recorded according to the present invention. If

divided time between the PCR-contained packets.

Accordingly, the HDVD player 400 can transmit recorded transport packets on time without parsing reproduced data to the level of a transport packet, that is, without decoding the contents of a transport packet.

The digital TV 500 compensates its own clock speed based on every the PCR difference value between two PCR-contained transport packets, and presents audio and video signals after determining the presentation time of the received transport packets based on the compensated self clock, thereby conducting video and audio presentation with no discontinuities.

If there is no transport packet to record PCR in a certain pack, the time reference to send the first transport packet TP1 of the pack is recorded in the transport time reference information fields 'SYS\_PCR\_base' and 'SYS\_PCR\_ext' instead of a PCR, and the value of 0000b is recorded in the packet location field 'PCR\_PKT\_POS' of the pack. Accordingly, the HDVD player 400 can obtain transport time references more often compared with the PCR-only recording embodiment when reproducing such-recorded HDVD-ROM, thereby adjusting the transport time interval between transport packets more accurately.

FIGS. 9 and 10 show another embodiment for creating and recording transport time reference information according to the present invention, which records the location information only for PCR-containing transport packets in the packet location field 'PCR\_PKT\_POS'. Where a PCR is recorded in the first transport packet TP1 of the first pack HD\_PCK #1 and in the third transport packet TP3 of the second unit pack HD\_PCK #2, the value 0001b for the first location is recorded in the packet location field of the first pack header, and the value 0011b for the third

location is recorded in the applicable field of the second pack header.

Accordingly, when the HDVD player 400 reproduces such-recorded HDVD-ROM, the controller 46 searches for the PCR-contained transport packet indicated by the packet location field 'PCR\_PKT\_POS' of the pack header, reads out the PCR contained in the found packet, and uses the read PCR as a transport time reference for transmitting the found packet. In this embodiment, the controller 46 refers to the information of the TP header by decoding to the transport packet level.

FIG. 11 is another embodiment for creating and recording transport time reference information according to the present invention, which records the transport time reference information for the first transport packet of each pack. In this embodiment, it is not necessary to record the location information for a transport packet to be transmitted based on the recorded transport time reference information in the pack header since all transport packets related with the transport time reference information of the pack headers are fixed as the first.

If a PCR is recorded in the first transport packet, the value of the PCR is copied to and used as a transport time reference, whereas if a PCR is recorded in the third transport packet of the second pack as shown in FIG. 11, the time value of the PCR of third packet is ignored and the value for time reference to be used for the first packet is recorded in the fields of time base 'SYS\_PCR\_base' and time offset 'SYS\_PCR\_ext' as the transport time reference information.

Accordingly, when reproduction is proceeding, the controller 46 detects the transport time reference information written in fields 'SYS\_PCR\_base' and

'SYS\_PCR\_ext' of the pack header and transmits the first transport packet to the digital television 500 through applying the first packet to the TS MUX 45 at the time specified by the detected transport time reference

5 information. For the other packets except the first one, the time differences between transport time references recorded for two first packets of consecutive packs are equally divided, then each packet except the first one is transmitted at each divided point of time.

10 Instead of the first packet, it is possible to designate a packet in other position, for example the last one as a reference packet corresponding to transport time reference information recorded in the pack header.

FIG. 12 is another embodiment for creating and  
15 recording transport time reference information according to the present invention. In this embodiment, no information on the transport time reference and the packet location for a time-information-contained packet is recorded in the pack header.

20 Instead, a PCR is always recorded in the first transport packet of every pack when a program-recorded HDVD-ROM is manufactured. When such-manufactured HDVD-ROM is reproduced in the HDVD player 400, the controller 46 checks the header information of the first transport packet  
25 of every pack, reads out a recorded PCR, and transmits the first packet on time specified by the read PCR.

The method for creating and recording transport time reference information for a high-density disk recording medium according to the present invention can record the  
30 transport time reference information without decreasing recording efficiency too much, or use the PCR, which should be recorded in transport packets intermittently, as transport time reference information without recording
